© 2025

A substance, such as an antibiotic, that kills or stops the growth of microbes, including bacteria, fungi, or viruses; grouped according to the microbes they act against (antibiotics, antifungals, and antivirals). (CDC)

Any substance identified by the human immune system as "other" or "foreign," usually taking the form of a molecule originating from a bacterium or other invader.

The presence of microorganisms in or on a host with growth and multiplication but without causing any symptoms or disease.

The ability of microorganisms to grow when treated by a drug that was previously an effective antimicrobial agent.

The period of time from exposure to some infectious source to the development of signs and symptoms.

The proportion of other patients or residents colonized within a defined population or area.

The ability of an infectious agent to invade, survive in, and multiply in a host; can be calculated as the number of those infected divided by the number of those exposed.

The entry into and multiplication of an infectious agent in the tissues of the host and tissue damage resulting in apparent or unapparent changes in the host.

An imbalance of nutrients or stores compared to physiological requirements.

The time from exposure to the beginning of the infectious period.

Malnutrition that leads to individuals being overweight or obese.

Organisms that develop resistance to multiple antimicrobials, especially those that are traditionally used for treatment.

Malnutrition due to chronic inadequate intake of energy and protein.

The ability of an infectious agent to cause clinically apparent disease in infected hosts; calculated as the number of those diseased divided by the number of those infected.

The measure of a microbe's ability to invade and create disease in a host, determined by characteristics that relate to the favored site of invasion, disease induction, and avoidance of host resistance.

A bacterial or fungal infection of the urinary tract.

Glycocalyx

APIC LTC-CIP Learning System

© 2025

Attached, architecturally defined, three-dimensional environments that may contain either single or multiple species of microorganisms.

Free-living, single-celled organisms that multiply through chromosomal replication and cellular division.

Cell structures composed of nuclear material and protein that enable bacteria to survive extreme conditions.

An organized glycocalyx that is firmly attached to the cell wall.

Toxins that are secreted by bacteria, mainly those that are Gram-positive.

Surface components (complexes of bacterial proteins, lipids, and polysaccharides remaining firmly in the bacteria) of Gram-negative bacteria.

Chemical substances that surround cells.

A term that refers generically to all members of the kingdom fungi.

Resident flora

APIC LTC-CIP Learning System

© 2025

Bacteria in which the cell wall consists of many layers of peptidoglycan, forming a thick rigid structure.

Bacteria in which the cell walls contain only one (or very few) layers of peptidoglycan.

Infections or diseases caused by fungi.

Usually reproduce by elongation and fragmentation of their hyphae (or pseudohyphae), which are tube-like projections; they produce fluffy, cottony, wooly, or powdery colonies.

An organism that lives on or within another organism and obtains an advantage at the expense of the host.

Microbes that normally live in and on the body without causing infection or disease to the host.

Normal flora that are always present on the skin and throughout the body, including the body's colonizing bacteria.

Infectious particles of abnormally folded proteins that do not contain DNA or RNA.

Normal flora that colonize the skin and mucosa temporarily, without invading tissues.

An unorganized glycocalyx that is loosely attached to the cell wall.

The measure of a microbe's ability to invade and create disease in a host, determined by characteristics that relate to the favored site of invasion, disease induction, and avoidance of host resistance.

Intact viral particles made up of nucleic acid (either RNA or DNA), a protein coat (capsid), and possibly an envelope composed of viral proteins and host cell lipids.

Unicellular, round to oval organisms ranging in size from 2 to 60 millimeters.

Obligate intracellular parasites that require living host cells to grow and reproduce and are dependent on the cells' synthetic and metabolic machinery.

An efficient mode of transmission that may involve varying distances between the source and the host.

A component of the epidemiological triangle; may be a bacteria, virus, fungus, protozoan, helminth, or prion.

© 2025

The relationship between a risk factor and an outcome, such as a disease.

A report that summarizes typical patterns of susceptibility to antibiotics by specific species of bacteria.

A biological, physical, or chemical entity capable of causing disease.

A person who shows no recognizable signs or symptoms of a disease but is capable of spreading the disease to others.

A group of persons with a given disease occurring in the same space and time but not epidemiologically linked. If an epidemiological link is made, may become an outbreak.

Persons who may continue to have organisms present for very long periods of time.

Those who have recovered from a disease but still have organisms present that can be transmitted.

An infection that is present on admission to a healthcare facility and has no association with a recent hospitalization.

External vector-borne transmission

APIC LTC-CIP Learning System

© 2025

A mode of transmission that features person-to-person spread with actual physical contact occurring between a source and a susceptible host.

A laboratory technique used to grow (cultivate) bacteria and yeast.

The usual incidence of a given disease within a geographical area during a specified time period.

A mode of transmission that occurs when the infectious agent spends only a brief period passing through the air and can be inhaled at that time.

An excess over the expected incidence of disease within a given geographical area during a specified time period.

A component of the epidemiological triangle; consists of all external factors associated with the host.

The mechanical transfer of microorganisms by a vector, such as a fly on food.

The study of the distribution and determinants of disease and other conditions in human populations.

subclinical

APIC LTC-CIP Learning System

© 2025

An infection that is not present at the time of admission to a healthcare facility but is temporally associated with admission to or a procedure performed in the facility; may also be related to a recent hospitalization.

An inanimate object on which organisms may exist for some period of time, for example, a contaminated piece of medical equipment.

A component of the epidemiological triangle; refers to a human or other animal.

The resistance of a group to invasion and spread of an infectious agent, based on the immunity of a high proportion of individual members of the group.

A mode of transmission that occurs when a patient comes in contact with a contaminated intermediate object or fomite.

The number of new cases of a given disease in a given time period.

An infection that runs a course similar to that of clinical disease but below the threshold of discernible clinical symptoms.

An infection that results in clinical signs and symptoms of a recognizable disease process.

Persons who periodically shed organisms.

In antimicrobial susceptibility testing, level at which a drug is likely to be effective only at body sites where it is physiologically concentrated or at other body sites if higher-than-usual dosing regimens are used.

The method by which an organism reaches a susceptible host.

Involves the transfer of infectious material directly from the vector into the new host, such as occurs with mosquitoes and malaria.

An epidemic spread over a wide geographical area, across countries or continents.

Synonymous with epidemic but often preferred when dealing with the public; in local settings, a group of people with the same disease who are epidemiologically linked.

In the chain of infection, the path by which an infectious agent leaves the reservoir.

In the chain of infection, the means by which an infectious agent enters a susceptible host.

A place in which an infectious agent can survive but may or may not multiply, for example, *Pseudomonas* in nebulizers and hepatitis B on the surface of a hemodialysis machine.

The number of existent cases of a given disease at a given time.

The probability or likelihood of an event occurring.

In antimicrobial susceptibility testing, level at which a drug is unlikely to be effective for the treatment of infection unless predictably toxic dosages are used.

Describes whether an identified organism is able to be treated successfully using a given antimicrobial.

A characteristic, behavior, or experience that increases the probability of developing a negative health status (e.g., disease, infection).

Persons who may continue to have organisms present for very long periods of time.

In antimicrobial susceptibility testing, level at which a drug is likely to be effective for the treatment of infection using a standard dosage.

A disease transmitted from animals to humans (e.g., cat scratch fever, psittacosis).

In biology, a biting insect, tick, or other organism responsible for transmitting a disease, pathogen, or parasite between persons, animals, or plants.

A SARS-CoV-2 vaccine consisting of two SARS-CoV-2 strains targeted to specific variants.

Arises when a person is exposed to an organism by either vaccination or direct exposure; when the immune person comes into contact with the organism in the future, the immune system will remember it and trigger an immune response.

Objects or instruments that must be free of any microorganisms, including bacterial spores, when they enter sterile tissue, bone, or the vascular system in order to not introduce microorganisms into the site that would result in an infection or a disease.

The removal of foreign material (e.g., soil, organic material) from objects; required before disinfection and sterilization can occur since foreign material interferes with the effectiveness of these processes.

Infection control interventions designed to reduce transmission of multidrug-resistant organisms in nursing homes. (CDC)

Thermal or chemical destruction of pathogenic and other types of microorganisms.

A vaccine consisting of a single strain or type of organism.

A process by which a person becomes protected against a disease through vaccination.

Conveyed through administration of antibodies for a specific disease or administration of certain blood products; results in immediate immunity.

Medical devices and other items that come in contact with intact skin but not mucous membranes.

An influenza vaccine consisting of four influenza strains (e.g., two A virus strains, two B virus strains).

A vaccine consisting of multiple strains or types of organisms (e.g., 23-valent pneumococcal vaccine).

A series of evidence-based procedures, used for all patients in all settings, to reduce the presence of microbiological agents in a healthcare facility and to prevent cross-contamination between HCP, patients, and the environment.

Medical devices that come in contact with mucous membranes or nonintact skin; should be free of all microorganisms (i.e., mycobacteria, fungi, viruses, bacteria), although small numbers of bacterial spores may be present.
